Received 10 February 2011; accepted 24 February 2011

Key indicators: single-crystal X-ray study; T = 293 K; mean  $\sigma(C-C) = 0.009$  Å; R factor = 0.068; wR factor = 0.238; data-to-parameter ratio = 13.2.

In the title compound,  $\{[Ni(C_{12}H_{10}N_2)(H_2O)_4](NO_3)_2\}_n$ , the Ni<sup>II</sup> ion, lying on a crystallographic inversion center, has a distorted octahedral coordination sphere comprising four water ligands and two N-atom donors from the trans-related 1,2-bis(4-pyridyl)ethene ligands, which also have crystallographic inversion symmetry. These ligands bridge the Ni<sup>II</sup> complex units, forming chains extending along the [110] and  $[\overline{1}10]$  directions. The nitrate counter-anions stabilize the crystal structure through water-nitrate O-H···O hydrogen bonds.

#### Comment

The interaction of transition metal ions with biologically active molecules such as amino acids and various acids is very important in biological systems (Daniele *et al.*, 2008; Parkin, 2004; Tshuva & Lippard, 2004). In attempting to model the interaction, we have extensively studied the interaction of the transition metal carboxylates e.g. copper(II), cadmium(II), and zinc(II) benzoates with a variety of spacers such as quinoxaline, 6-methylquinoline, 3-methylquinoline, *trans*-1-(2-pyridyl)-2-(4-pyridyl)ethylene, and di-2-pyridyl ketone (Lee *et al.*, 2008; Yu *et al.*, 2008; Park *et al.*, 2008; Shin *et al.*, 2009; Yu *et al.*, 2010; Kim *et al.*, 2011). However, nickel as a metal ion source has rarely been used. In this work, we have employed nickel(II) trimethylacetate as a building block and *trans*-1,2-bis(4-pyridyl)ethene as a ligand. We report here on the structure of a new complex poly[tetraqua[*trans*-1,2-bis(4-pyridyl)ethene]nickel(II) dinitrate].

In the crystal structure of the title compound,  $[Ni(C_{12}H_{10}N_2)(H_2O)_4]$ .  $2(NO_3)]_n$ , the  $Ni^{II}$  ion lies on a crystallographic inversion center with the distorted octahedral coordination sphere comprising four water ligands and two N donors from the *trans*-related 1,2-bis(4-pyridyl)ethene ligands, which also have crystallographic inversion symmetry (Fig. 1). These ligands bridge the  $Ni^{II}$  complex units to form a one-dimensional chain structure. The nitrate counter-anions stabilize the crystal structure through water  $O_{mitrate}$  hydrogen bonds (Table 1).

#### **Experimental**

 $36.4 \text{ mg} (0.125 \text{ mmol}) \text{ of Ni(NO}_3)_2 \cdot 6H_2\text{O} \text{ and } 29.0 \text{ mg} (0.25 \text{ mmol}) \text{ of (CH}_3)_3\text{CCOOH} \text{ and } 29.5 \text{ mg} (0.25 \text{ mmol}) \text{ of NH}_4\text{OH}$  were dissolved in 4 ml of methanol and carefully layered with 4 ml of a chloroform solution of *trans*-1,2-bis(4-pyridyl)ethene (47.0 mg, 0.25 mmol). Crystals of the title compound suitable for X-ray analysis were obtained within a month.

#### Refinement

H atoms were placed in calculated positions with C—H distances of 0.93 Å (pyridyl) and included in the refinement with a riding-motion approximation with  $U_{iso}(H) = 1.2U_{eq}(C)$ . The water H atoms were located in a difference Fourier, and refined isotropically with O—H restraints (0.93 Å).

### **Figures**

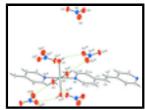

Fig. 1. A fragment of one-dimensional chain structure of the title compound showing the atom numbering scheme. Displacement ellipsoids are drawn at the 30% probability level. Inter-species hydrogen bonds are shown as dashed lines. For symmetry codes: (i) (-x + 1, -y + 1, -z); (ii) -x, -y + 2, -z). For other codes, see Table 1.

Special details

**Geometry**. All e.s.d.'s (except the e.s.d. in the dihedral angle between two l.s. planes) are estimated using the full covariance matrix. The cell e.s.d.'s are taken into account individually in the estimation of e.s.d.'s in distances, angles and torsion angles; correlations between e.s.d.'s in cell parameters are only used when they are defined by crystal symmetry. An approximate (isotropic) treatment of cell e.s.d.'s is used for estimating e.s.d.'s involving l.s. planes.

**Refinement.** Refinement of  $F^2$  against ALL reflections. The weighted R-factor wR and goodness of fit S are based on  $F^2$ , conventional R-factors R are based on F, with F set to zero for negative  $F^2$ . The threshold expression of  $F^2 > \sigma(F^2)$  is used only for calculating R-factors(gt) etc. and is not relevant to the choice of reflections for refinement. R-factors based on  $F^2$  are statistically about twice as large as those based on F, and R- factors based on ALL data will be even larger.
